

Monte Carlo Analysis of the Dose Enhancement in the Scalp of Patients due to Titanium Plate Backscatter during Post-Operative Radiotherapy

Michael T. Hardin

Motivation

- It has been reported that patients receiving post-operative radiotherapy are demonstrating necrosis of the scalp superior to the placement of titanium fixation plates.
- Healthy scalp tissue is approximately 3-5 mm thick.
- Patients' scalp tissue have become paper-thin and fragile, requiring surgery.

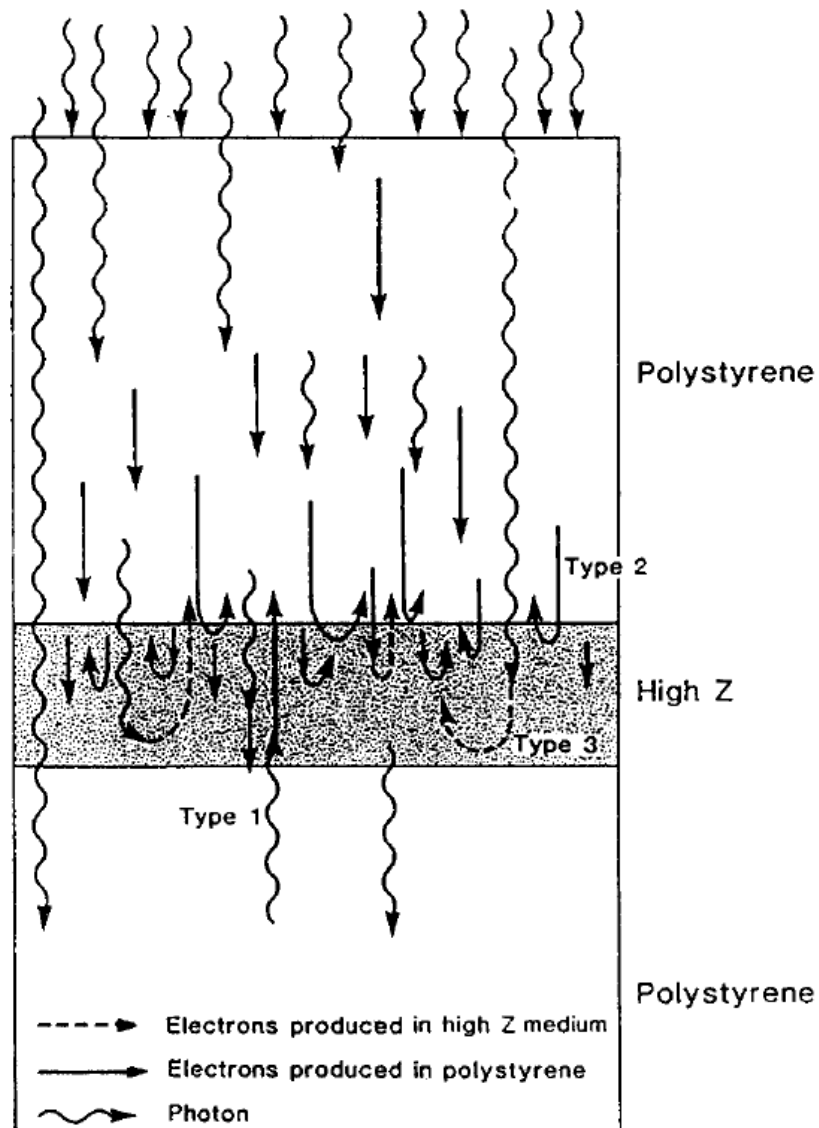

- Synthes and Biomet titanium plates of thickness 0.4 mm and 0.38 mm respectively.

Motivation

- This is a clinically significant issue.
- Why is this issue occurring?
- What is the dose enhancement to the scalp?
- How can this issue be remedied?

Theoretical Considerations

- Das & Kahn, 1989 divide the backscattered dose at an interface into the dose due to:
 - (a) the backscattered photons
 - (b) the backscattering of secondary electrons set in motion in the soft tissue medium above the inhomogeneity
 - (c) the backscattering of secondary electrons set in motion within the inhomogeneity

Theoretical Considerations

- The backscattered dose at interfaces in a photon beam is primarily due to secondary electron backscattering.
- The backscatter dose factor is nearly independent of field size, photon energy, and thickness above the inhomogeneity; saturates quickly with thickness of the inhomogeneity.

BSDF vs atomic number of the inhomogeneity

Clinical Measurements

- Kodak EDR2 and ISP Gafchromic MD-55 film were used to quantify the dose enhancement.
- Titanium plates were placed inside the film packets to replicate the clinical scenario.
- Different amounts of buildup were examined.
- Films were scanned and analyzed in RIT.

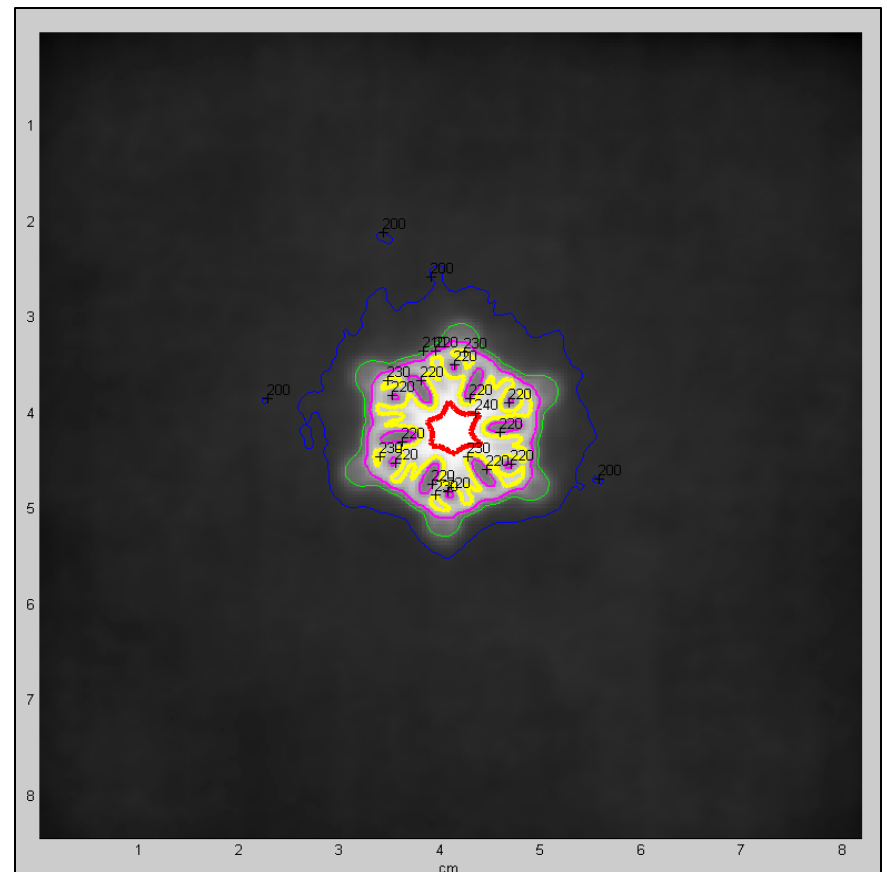

- Placement of the titanium plate.

- Phantom setup.

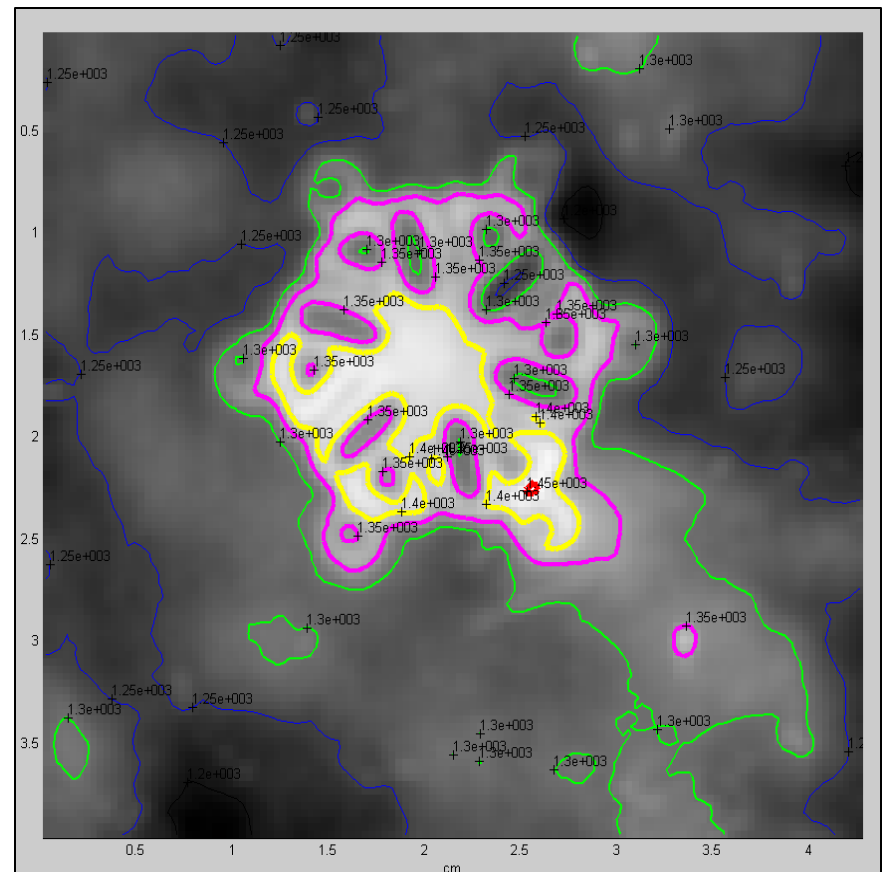

- Film processing and analysis in RIT.

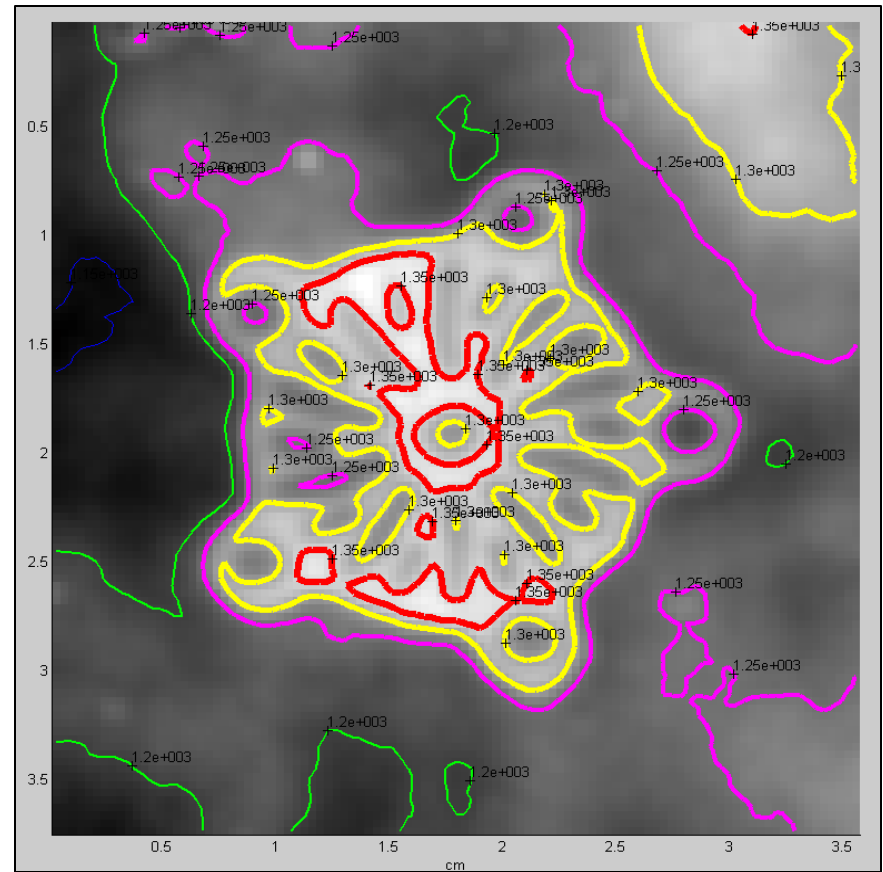

- Results for EDR film ranged from 5% to 22%.

- Film processing and analysis in RIT.

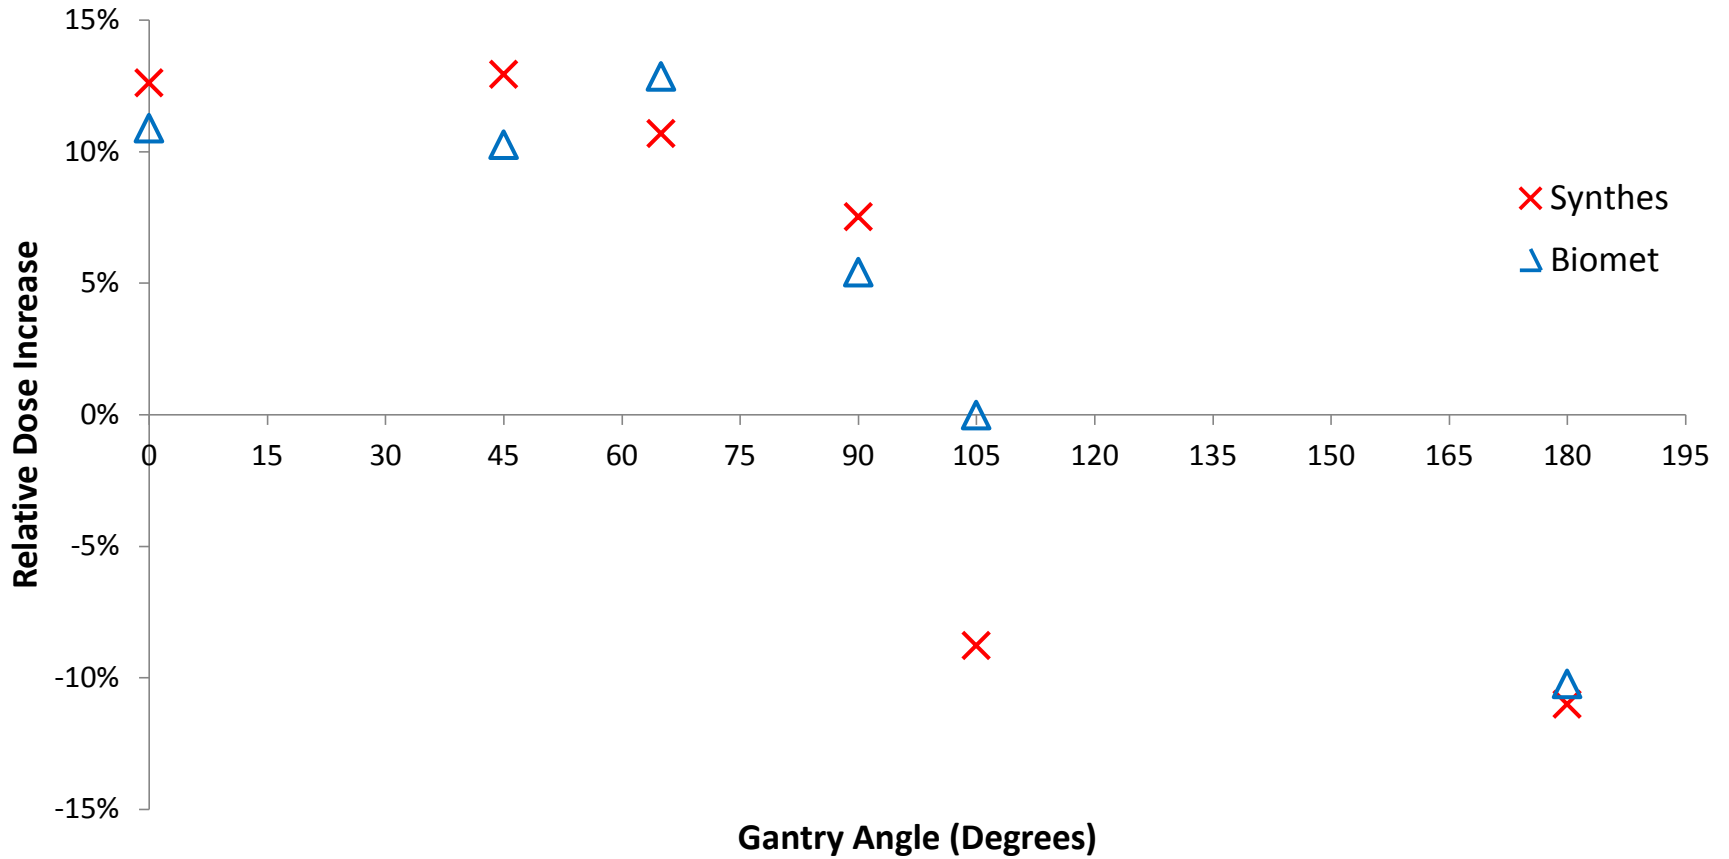

- Results for Gafchromic film and Synthes plate ranged from 8% to 13%.

- Results for Gafchromic film and Biomet plate ranged from 0% to 13%.

Gafchromic Film

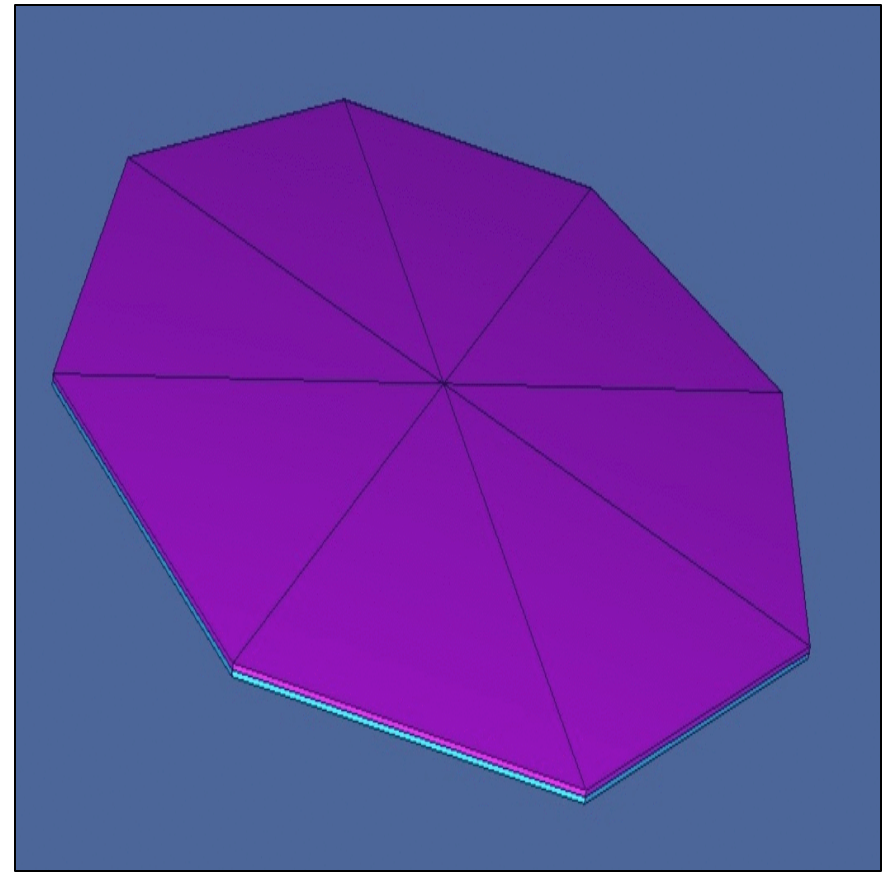

Relative Dose Increase vs Gantry Angle

Monte Carlo Modeling

- MCNPX was used to model and simulate the transport of photons and electrons within a box of water containing a thin titanium plate.
- Shimozato et al., 2010 found the maximum relative differences between simulation and TPS results on the entrance and exit sides of the plate to be 23.1% and -12.7% respectively.

- Dynamic 3D plotting in MCNP Visual Editor.

Relative Energy of Deposited Radiation

Conclusion

- The maximum relative dose enhancement on the entrance and exit sides of the plate are 26.4% and 7.1% respectively with error $< 1\%$.
- Future work involves research and development of improved surgical fixation devices and/or techniques. Additionally, what biological mechanisms are responsible for this effect?
